

ExCalibre January 2023 release:

ExCalibre introduces three new features which boost its performance and provide you with more calibration options:

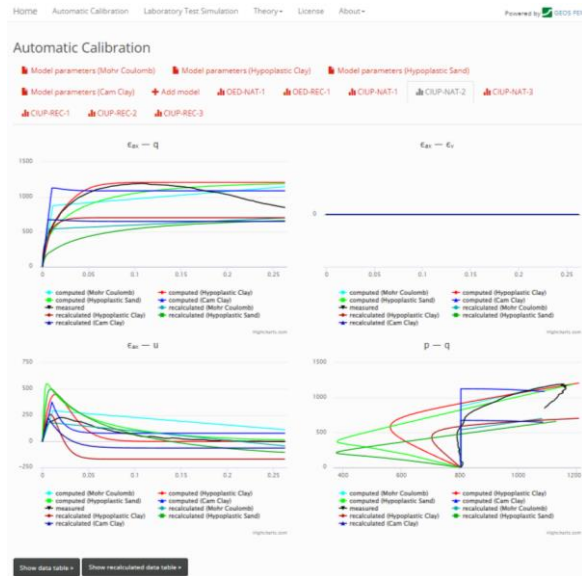

- 1) New calibration option of the Mohr-Coulomb model was added in to the group of already available constitutive models.

- 2) All the available constitute models can be now included in the calibration and the results can be compared against each other and against the input data.

You can still modify the calibration results for each individual constitutive and inspect the results.

- 3) Some parameters can be often determined more precisely with experiments that are not available or considered in ExCalibre. Therefore, new option “Fix parameter” is now available in ExCalibre. Any parameter of any available constitutive model can be now fixed and the remaining parameters will be calibrated base on this preference.

The screenshot shows the 'Automatic Calibration' interface with the 'Calibration input' form. The form includes a 'Laboratory protocol file' field with a search button, a 'Material model' dropdown menu set to 'Hypoplastic Clay', and a 'Fix selected parameters' section. This section contains several input fields for parameters: k , n , m , p , α , β , γ , δ , ϵ , ζ , η , θ , ϕ , ψ , ω , χ , ψ , ω , χ , ψ , ω , χ . Below the input fields is a 'Calibrate' button. At the bottom, there are links to 'Download clay template', 'Download sand template', 'Download other examples from ExCalibre soil database', and 'Close ExCalibre'.

Works on Excalibre are still undergoing and we plan to introduce more changes in the future.
